Backstory MCP Server

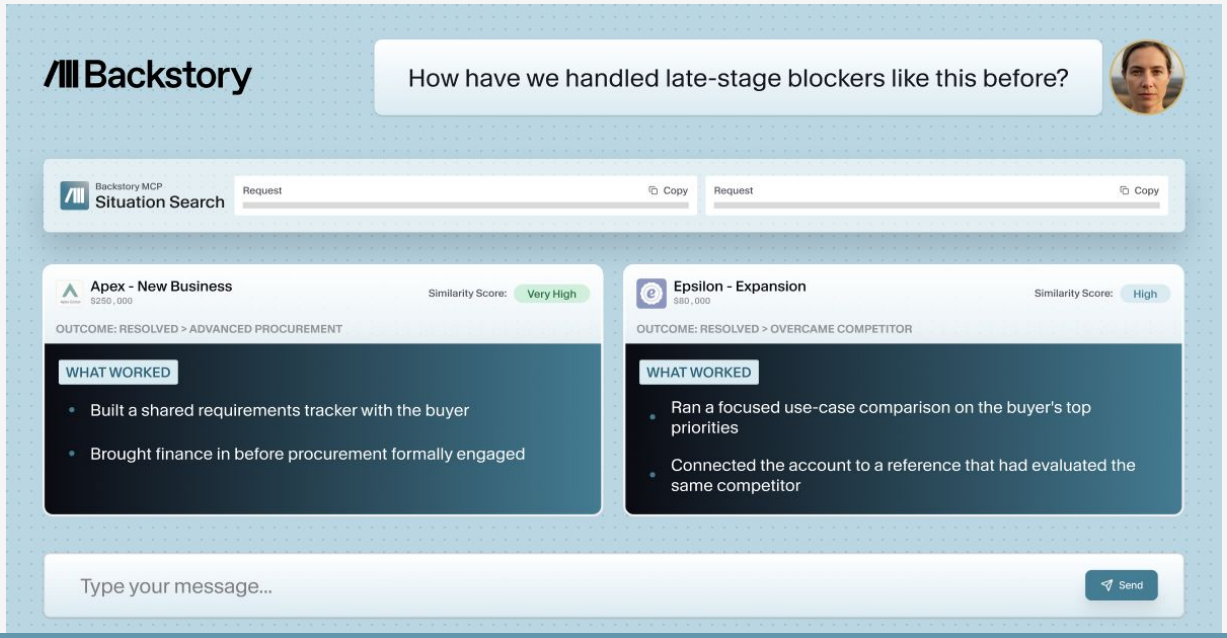

Built for agents. Not retrofitted for them.

AI agents reason over whatever you feed them. Feed them partial, stale, or mismatched data - and they give you confident wrong answers about your most important deals.

The question isn't whether your agent can access revenue data. It's whether that data is complete, current, and matched to the right deals.

"We'll build it ourselves."

The easy 30% is piping emails and transcripts into an LLM. The hard 70% is everything around it. Entity resolution at enterprise scale means handling shared domains, M&A entities, and contacts that map across multiple open opportunities. Get it wrong and your agent is answering questions about the wrong deals. Most teams discover this after they've shipped the easy version.

The question to ask every MCP vendor:

"Is this a distillation, matching, and filtering layer built to run an agent on enterprise revenue data - or is it a summary tool with an API on top?"

Three gaps call recording MCPs don’t close

Call Recording Scope

Not all signals are equal. Who said it and whether they have buying power determines what it means. Call recording tools capture activity. They don't know what it means.

Call Recording Cadence

Call summaries update when calls happen. Deals don't - they move on every email reply, every follow-up that didn't land, every new stakeholder who got CC'd.

Call Recording Shape

One meeting. One readout. One altitude. "Catch me up on this account" and "how did this risk materialize" are different questions. A call summary answers neither.

Why Scope is Hard

Matching email to the right opportunity at enterprise scale means handling shared domains, M&A entities, partner motions, and contacts that map to multiple open opportunities at once. Semantic filtering keeps PHI and personal threads out of the pipeline entirely - keyword blocklists don't.

Why Cadence is Hard

Every signal - including the follow-up that never came - has to register as an update to the opportunity story in real time. Not a new document per meeting. Not a batch job. A single living object per opportunity that compounds with every new activity.

Why Shape is Hard

Different agent questions need different distillation shapes. "Catch me up" needs a narrative. "How did this risk materialize" needs a causal trace. "Who are my active champions" needs a relationship map. Building those shapes requires knowing what questions agents actually ask revenue leaders - which only comes from operating this problem at enterprise scale.

Backstory Scope

Score-based NLP matching, configurable against your CRM schema and GTM motion. Test rule changes against historical activity before deployment. Multi-CRM is native. Semantic filtering evaluates every message individually - non-business content never reaches the pipeline.

Backstory Cadence

Every email, meeting, and signal - including the follow-up that never came - appends to a single evolving revenue story per opportunity. The agent reads one coherent object, current as of the last activity. Not ten standalone summaries stitched together.

Backstory Shape

Multi-altitude distillation built for the questions revenue leaders actually ask agents. The shapes exist for "catch me up," "how did this risk materialize," and "who are my active champions" - because Backstory has been operating this problem at enterprise scale since before MCP existed.

Backstory has been solving the matching, filtering, and enrichment problem for enterprise revenue teams since 2016. The infrastructure isn't new. It's never mattered more.
